Abstract— The aim of this work is to demonstrate the usefulness of the artificial intelligence tools for early diagnostic of diseases. From the historic and simple assessment of temperature by the clinical thermometer, thermal imaging camera has opened up new perspectives, and that a whole image field-of-view can be characterized in a single measurement. Thermographic assessment of temperature distribution within the examined skin enables a quick, non-contact, non-invasive relative measurement of their temperature. This work shows that the output predicted using the artificial neural network based on thermography, can be used for early detection of diabetes.

Index Terms — *Thermal Imaging camera, artificial neural networks (ANN), diabetes.*

I. INTRODUCTION

According to the World Health Organization, in 2009, approximately 347 million were infected with the diabetes, and it is expected that in 2030 the number will reach about 500 million [1]. Abnormal skin temperature is a natural indicator of illness [2]. The human skin temperature distribution of a healthy body exhibits a contralateral symmetry [3]. Thermography is a reliable non-invasive technique for imaging skin temperature distribution. It is a remote and a non-contact temperature measuring technique that enables simultaneous monitoring a large area of the human skin surface. Infrared thermal imaging, unlike many other imaging techniques used in medicine, is not an internal imaging system for anatomical information. The human skin surface is a highly efficient radiator, with an emissivity of 0.98 [4]. This technology has the benefits of no material placed on a human skin surface, and that a whole image field-of-view can be characterized in a single measurement. Several applications of thermography in medical science has been highlighted in [2]. Thermography has been extensively used for diabetic neuropathy, breast cancer detection, fever screening, brain imaging and assessment of radiation damage to human body [2]. Bagavathiappan et al. [5] used the thermal imaging camera to study the plantar foot temperatures of 112 patient subjects with type 2 diabetes selected from a tertiary

diabetes center in South India. They indicated that thermography can be used as an additional tool for evaluation of high risk diabetic feet. However, assessing thermal images is a complex and subjective task that can be greatly facilitated by artificial intelligence techniques.

Most of medical imaging procedures have benefited from the use of modern artificial intelligence systems [6]. An artificial intelligence system is a system that can make decisions which would be considered intelligent if made by a human being. Artificial Intelligence (AI) is becoming more popular and particularly amenable to modelling complex systems, because it has demonstrated superior predictive ability compared to traditional methods. To find the relationship between inputs and outputs of a complex system, artificial neural network (ANN) techniques have drawn more attention rather than statistical models, and produce results without requiring a detailed description of the phenomena that is governing the system. There are different ANN architectures to building thermal models, Back-Propagation (BP) artificial neural network modelling has proven to be a suitable nonlinear modelling method.

Human skin temperature, the information that can be investigated by the thermograph, is dependent on blood circulation. In ischemic conditions, where blood perfusion may be reduced, especially at the periphery of the human body and limbs (hands and feet), reduced temperature may be found. This requires a period of stabilization, where the patient is resting in the stable room temperature for a period of time prior to examination. During this time, areas of the body to be examined must be unclothed [4].

Medical thermography is used as a screening method for early detection of cancer and diabetes, but the use of this technology in Libya has still not been researched. This work presents a technique for early diagnostic of diabetes using thermal imaging camera and artificial neural networks, in order to facilitate the physician's decision making. First, the thermal images are pre-processed to reduce the noise introduced during the initial acquisition. Then, potential

regions of interest are identified using imaging process tools such as isothermal analysis and segmentation techniques. Finally, the proposed ANN model was used to predict the patient status.

II. MATERIAL AND METHODS

A. Thermal Imaging Camera

A thermal imaging camera provides a visible image of otherwise invisible infrared light that is emitted by all bodies due to their thermal status. Thermography is a reliable non-invasive technique for imaging skin temperature distribution. The thermal imaging camera has become a powerful tool for researchers and has applications in various fields such as medicine, biometrics, computer vision, building maintenance and so on [7, 8]. In this paper, a medium-specification thermal imaging camera, namely an FLIR ONE™, was used to record a sequence of thermal images of temperature distributions across the patient foot. This camera provides a sensitivity of 0.1 °C, and a scene temperature range -20 °C - 120 °C. Full camera specifications are provided in Table 1. The thermal imaging camera offers a continuous picture of the temperature distribution in the image field-of-view. This is important as it provides the distribution of heat during the diagnostic period across the whole patient body. This allows the patient skin to be measured online during the diagnostic period. As well as the camera providing live continuous thermal images, they can also be recorded for further analysis. The thermal images are saved as a matrix of temperatures with a specific resolution of one pixel (equivalent to 5.50 mm²), which equates to over 38000 temperature measurement points for this 160 x 120 resolution camera. These thermal images can be transferred to a personal computer for analysis. Figure 1 shows a general overview of the diagnostic setup.

TABLE 1: THERMAL IMAGING CAMERA SPECIFICATION.

Price	1750 Libyan dinar
Operating Temperature	32°F to 95°F (0°C to 35°C)
Weight	29 grams
Dimensions (L × W × H)	2.8 inches (72mm) × 1 inch (26mm) × 0.7 inches (18mm)
Device Compatibility	160 × 120 resolution thermal accessory with MSX for iPhones / iPads with a lightning connector

B. Artificial Intelligence (AI) model

Artificial neural network as a form of AI is a data-driven approach. It is designed in a way that mimics the behavior of biological neural network. A typical artificial neural network has an input layer, one or more hidden layers, and an output layer [9]. The neurons in the hidden layer, which are connected to the neurons in the input and output layers by adaptable weights, enable the ANN to compute complex associations between the input and output variables [10]. The inputs of each neuron in the hidden and output layers are summed, and the resulting summation is processed by an activation function [10]. Training the model is the process of determining the adjustable weights, and it is similar to the process of determining the coefficients of a regression model by least squares approach. The weights are initially selected randomly and an optimization algorithm is then used to find the weights that minimize the differences between the model-calculated and the experimental outputs [11]. Across the whole modelling procedure, no physical equation is used (see Figure 2).

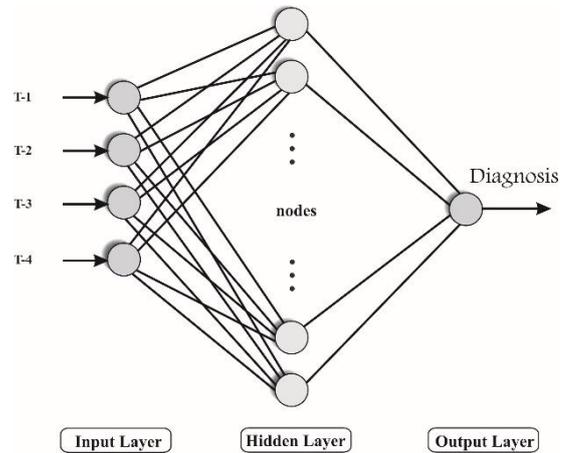

Figure 2: Basic structure of ANN model.

III. RESULTS AND DISCUSSION

In this paper, the data has been analyzed using MATLAB. One disadvantage of thermal imaging is that it can have low absolute accuracy, usually in the order of ±2 °C. A number of MATLAB functions have been developed to enhance this accuracy, including averaging the images to reduce pixel noise, alignment of images and extraction from the temperature data by averaging groups of pixels at a specific point (see Figure 3).

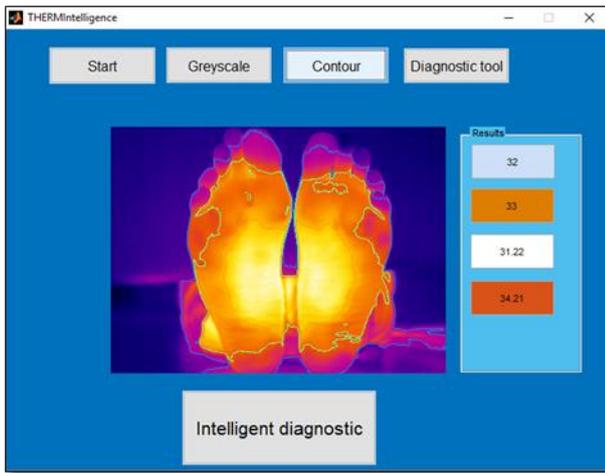

Figure 3: Intelligent diagnostic system.

The radiation measured by the thermal camera depends on the temperature of the body, but is also affected by the emissivity of the body skin. Additionally, radiation reflects from shiny surfaces, and is directly captured by the thermal camera and appearing as very hot areas. In order to measure the temperature of the body precisely it is therefore, necessary to know the emissivity accurately, for which the application of masking tape with a known emissivity (0.95) is a common and effective solution. The camera parameters are then set according to the measurement conditions considering the emissivity of the skin human body, the distance between the body and the camera, the relative humidity and the ambient temperature, as illustrated in Table 2.

TABLE 2: THERMAL IMAGING CAMERA PARAMETERS.

Distance	1.5 m
Emissivity	0.98
Ambient temperature	23 °C
Relative humidity:	30%

A. Case study

In order to illustrate the application of the model in automated detection of diabetic foot, we used simple case study and calculate the model. The model is conducted on realistic data from 90 patients. Due to low accuracy of our FLIR ONE™ camera, 85 exams were performed from 1 February to 30 June 2013 in the Dos de Mayo hospital [1], and 5 exams were performed in the Misurata hospital. In order to optimize the ANN coefficients, the exam’s dataset was divided into two sets, one is being used for training the model (approximately 60 %), and the rest for testing performance (approximately 40 %). Four temperature spots are used as inputs, and a patient’s status as output.

Usually ANN models have three layers: Input, hidden and output layer. Although, for common engineering problems, one hidden layer is sufficient for model training [12, 13], two or more hidden layers may be needed for other applications

[14]. An ANN model with three layers was used in this paper: the input layer has 4 input variables and the output layer has one neuron (the diagnosis).

Selection of the number of neurons in the hidden layer is important for finding a suitable ANN model structure. Although increasing the neuron numbers in the hidden layer, may help to improve the neural network performance, however, the possibility of over-fitting may increase. Furthermore, a large number of hidden neurons can increase model training time. In this paper, different ANN models were evaluated using Root-Mean-Square Error (RMSE), in order to measure the deviation between the training data and predicted values. In Figure 4 the RMSE of ANN model for the training data is plotted versus the epochs. It is observed that after 5 epochs were used, the performance does not improve any further. Before generating the final model, it is essential to obtain the optimum number of neurons in the hidden layer. For this purpose, several ANN models can be constructed with a different number of neurons. The optimum size of the model structure was determined, and the results are summarized in Table 3. It was found that the ANN model with 10 neurons exhibited the lowest error RMSE=1.48 for testing dataset.

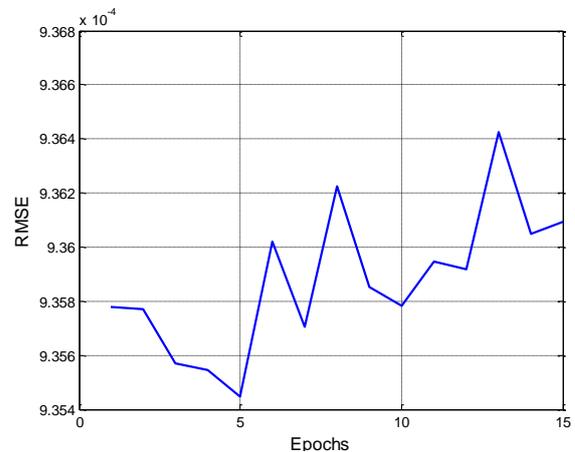

Figure 4: RMSE of the ANN model during training process.

The results of this study strongly suggest that recent improvements in thermography techniques and artificial intelligence tools have indeed contributed to increased performance when using such a system for early detection of some diseases such as diabetes and cancer. These early results using the proposed system are promising and further studies should be carried in this regard.

Table 3: Performance of ANN models.

Model	Number of neurons	Convergence epochs	RMSE of the training data	RMSE of the testing data
1	5	20	10.38×10-006	1.92
2	8	20	4.45×10-005	1.48
3	10	15	1.55×10-005	1.48
4	20	22	4.11×10-005	1.88
5	30	30	3.10×10-005	1.98

IV. CONCLUSION

In this contribution, we successfully used an ANN model and thermal imaging camera for early diagnosis of diabetic foot. As a result of the proposed method, the initial model can be sufficiently well defined to the point that it might only need a small number of training iterations. We believe that correlation between foot temperature change and diabetes as described in this paper deserves further analysis in Libya, in order to create a new tool for early diagnostic of diabetes and other diseases.

ACKNOWLEDGMENT
